

Spring Boot simplifies enterprise Java application development by providing an opinionated, convention-over-configuration framework that drastically reduces boilerplate setup. Its core capability is **auto-configuration**, which automatically configures Spring components based on the JAR dependencies detected on your classpath. It streamlines deployment through **embedded web servers** (such as Tomcat, Jetty, or Undertow), allowing applications to run as standalone executable JAR files without needing external application server installations. Build management is simplified using curated **starter dependencies** (spring-boot-starter-*) that bundle compatible library versions for specific application needs like web APIs, database access, or security. Additionally, Spring Boot delivers production-ready monitoring capabilities out of the box through **Spring Boot Actuator**, exposing health checks, metrics, and externalized environment configuration without requiring complex XML files or code generation.
